

WHITE PAPER

AI-DRIVEN FLIGHT RISK ASSESSMENT TOOL

DESIGN & DEVELOPMENT OF A SECOND-GENERATION AVIATION FRAT

Artificial intelligence (AI) and machine learning provide a unique opportunity to aviation safety by transforming flight risk assessment. Analyzing vast amounts of data in real-time, recognizing patterns, and making predictive recommendations, the AI-driven FRAT proposed in this white paper aims to continuously learn from new data inputs, dynamically adjusting risk parameters to provide more accurate and relevant assessments.

1. INTRODUCTION

In aviation's rapidly evolving landscape, safety remains paramount. The role of Safety Management Systems (SMS) and Flight Risk Assessment Tools (FRAT) in ensuring safety cannot be overstated. These tools enable operators to identify and mitigate risks proactively, thereby enhancing operational safety.

A Safety Management System (SMS) provides a structured approach for identifying hazards, assessing risks, and implementing risk control measures. Through SMS, aviation organizations can establish effective decision-making processes that bolster safety by planning, organizing, directing, and overseeing aviation operations.

Traditionally, aviation safety followed a reactive method, where accident analysis led to corrective measures. However, the SMS approach emphasizes proactive hazard detection, risk assessment, and mitigation, which can prevent incidents before they occur.

A FRAT, as a core component of an SMS, allows operators to systematically evaluate potential risks before each flight. By analyzing key factors—such as weather, pilot experience, and aircraft performance—FRATs offer operators a structured way to manage risks. The shift from reactive to proactive risk management represents not only a technological improvement but a cultural change that fosters safety-first operations.

2. PROBLEM DESCRIPTION AND SOLUTION OFFERED BY THE AI-DRIVEN FRAT

Current FRATs are limited by their reliance on static risk parameters and manual inputs. These tools often lack the real-time data integration and predictive capabilities needed to offer comprehensive risk assessments.

The proposed AI-driven FRAT addresses these shortcomings by:

- **Real-Time Data Integration:** The tool continuously pulls in live data (e.g., weather, pilot fatigue levels, and aircraft status) to ensure accurate, real-time assessments.
- **Dynamic Risk Parameters:** Machine learning algorithms allow the system to adapt to changing flight conditions, reducing the reliance on subjective pilot inputs.
- **Personalized Mitigation Strategies:** The system offers specific, actionable recommendations based on the unique characteristics of each flight, factoring in crew experience, company SOPs, and historical data trends.

This enhanced approach will not only meet regulatory requirements but also significantly improve flight safety by providing operators with more accurate risk assessments and tailored mitigation strategies.

TRADITIONAL FRAT

- : MANUAL INPUTS
- : SUBJECT TO POTENTIAL BIASES
- : STATIC PREDEFINED DATA
- : NUMERICAL RISK SCORING
- : LIMITED INSIGHTS
- : NO MITIGATION GUIDANCE

AI-DRIVEN FRAT

- : AUTOMATIC INPUTS
- : MINIMAL PILOT INTERACTION
- : REDUCED PILOT BIAS
- : DYNAMIC DATA PROCESSING
- : CONTINUOUS LEARNING
- : APP & EFB INTEGRATION
- : DYNAMIC RISK SCORING
- : RISK MITIGATION GUIDANCE

PROBLEM

SOLUTION

3. AVIATION SAFETY MANAGEMENT SYSTEMS & FLIGHT RISK ASSESSMENT TOOLS

HISTORY AND EVOLUTION

SMS MANDATES IN THE UNITED STATES

Safety Management Systems have been a cornerstone of aviation safety for decades, but their adoption has evolved over time. In 2015, the FAA issued 14 CFR Part 5, which mandated SMS for Part 121 air carriers, establishing fundamental safety requirements. However, a significant regulatory shift occurred in 2024, when the FAA expanded this mandate to include Part 135 operators (commuter and on-demand operations) and specific Part 91 operators (general aviation). These operators must implement SMS by May 28, 2027 to comply with FAA regulations.

This regulatory change reflects a growing recognition that both commercial and private aviation operators need comprehensive safety practices to manage aviation's inherent risks.

Flight Risk Assessment Tools: History and Evolution

Traditional Flight Risk Assessment Tools (FRATs) primarily use manual inputs, such as weather and pilot experience, to evaluate risk factors against a fixed scoring system. While these tools have improved safety, they suffer from several limitations:

- **Static data:** Traditional FRATs depend on predefined risk parameters that don't adjust dynamically to real-time changes.
- **Subjectivity:** Inputs from pilots, such as experience levels and personal risk tolerance, can introduce biases.
- **Limited insights:** Current FRATs primarily provide numerical risk scores without detailed guidance or mitigation strategies.

These limitations have prompted a rethinking of how FRATs should function in a modern, data-driven aviation environment. By leveraging artificial intelligence (AI) and machine learning, the next generation of FRATs can offer dynamic, data-driven risk assessments and personalized risk mitigation strategies that go beyond static scoring systems.

4. THE ROLE OF AI IN ENHANCING FLIGHT RISK ASSESSMENT

Artificial intelligence (AI) and machine learning are transforming flight risk assessment by analyzing vast amounts of data in real-time, recognizing patterns, and making predictive recommendations. The AI-driven FRAT proposed in this white paper aims to continuously learn from new data inputs, dynamically adjusting risk parameters to provide more accurate and relevant assessments.

The tool will leverage AI techniques such as natural language processing (NLP) to interpret unstructured text data (e.g., NOTAMs, pilot reports), computer vision to analyze visual data (e.g., weather patterns or airport conditions), and deep learning algorithms to recognize trends across diverse data sources. These include:

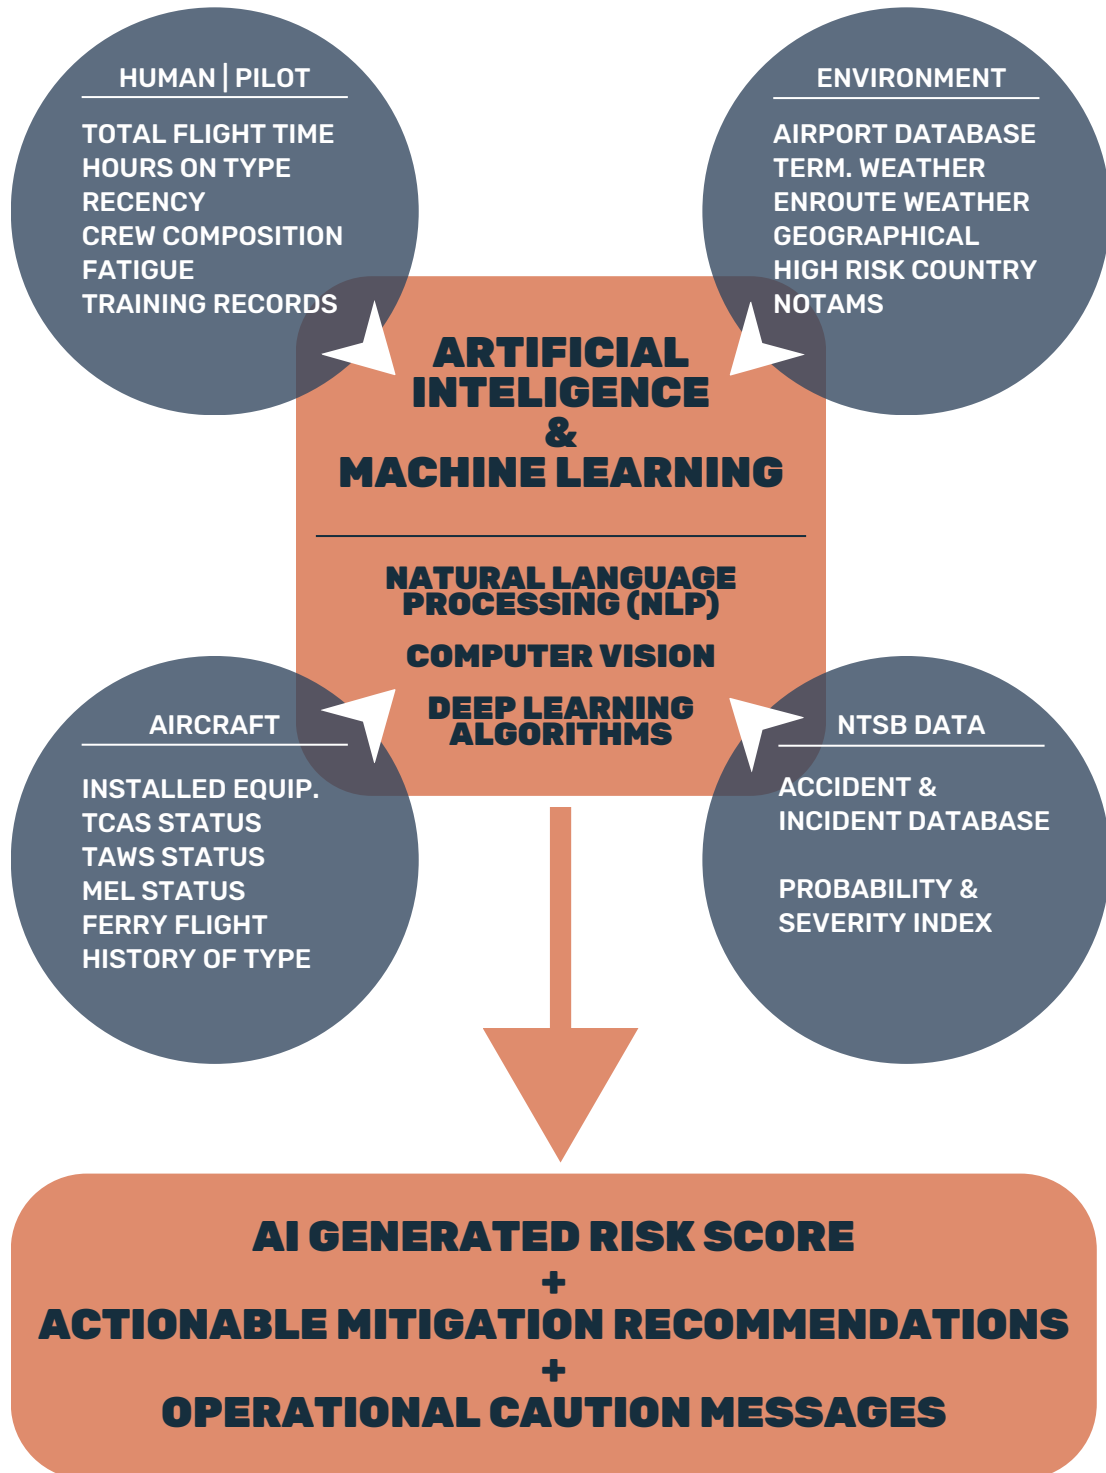

- Airport databases.
- Aircraft performance data & historical reliability.
- Real-time weather data, including turbulence, wind shear, and icing conditions, sourced from NOAA and other official providers.
- Historical accident/incident data from the NTSB.
- Pilot experience and training records from operator databases.
- Pilot fatigue, extracting duty roster and recent and long term activity.
- Current aircraft status, maintenance history, and performance data from CAMO systems.

By continuously analyzing these data streams, the AI-based FRAT can identify hidden risk factors and offer recommendations tailored to an operator's specific Standard Operating Procedures (SOPs) and company policies.

5. INPUTS NEEDED FOR COMPREHENSIVE FLIGHT RISK ASSESSMENT

To deliver comprehensive risk analysis, the AI-based FRAT tool integrates a broad range of data inputs. These inputs are analyzed using machine learning algorithms, providing operators with a real-time risk score and actionable mitigation recommendations.

6. RISK SCORING SYSTEM

A robust risk scoring system is essential for any FRAT. The AI-driven FRAT builds on traditional scoring methods by integrating real-time data and dynamically adjusting risk factors. For example, an initial risk score based on predefined parameters (e.g., pilot experience) will be continuously refined as new data –like updated weather forecasts, crew composition or airspace changes– become available.

This dynamic approach offers more accurate risk assessments compared to static FRAT systems, which rely solely on predefined risk factors.

7. RISK IDENTIFICATION AND MITIGATION OUTCOME

Once the risk score is calculated, the AI engine generates actionable recommendations. For example, if high levels of turbulence are detected along a route, the system might recommend altitude adjustments, alternate flight plans, or even delaying the flight. These recommendations are customized based on crew experience, aircraft capabilities, and company SOPs.

By offering tailored mitigation strategies, the AI-driven FRAT helps reduce human error and enhances decision-making, leading to improved safety outcomes. Final decisions and full responsibility remains with the Pilot-In-Command, but the generated information shall help making informed operational decisions.

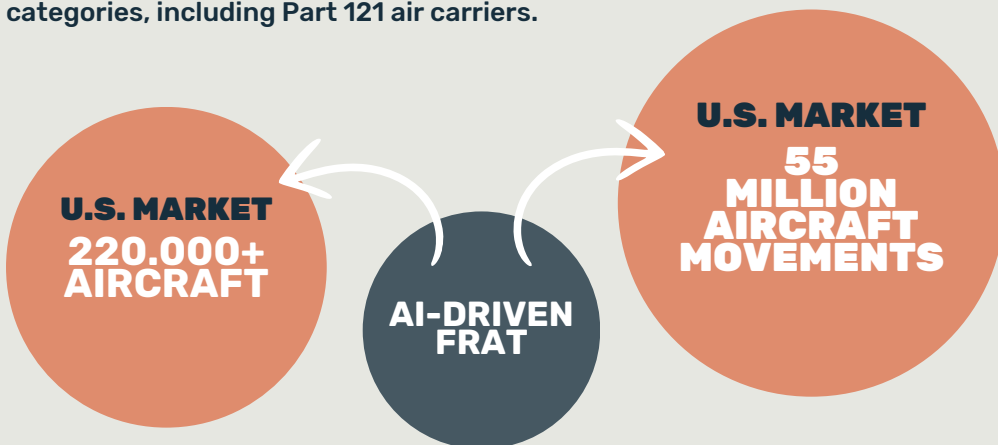

8. POTENTIAL CLIENTELE AND MARKET OPPORTUNITY

The primary clientele for the AI-based FRAT tool includes Part 91, Part 135, and Part 121 operators in the United States. Each of these segments represents substantial market opportunities:

- **Part 91 Operators:** Covering private, non-commercial aircraft operations, this market includes over 200,000 active private aircraft in the U.S. This category encompasses a broad range of operators, from individual pilots to large corporate flight departments.
- **Part 135 Operators:** This segment includes approximately 2,000 operators managing over 12,000 aircraft, such as air taxis and charter services. Operators in this category vary significantly in size, with some managing small fleets and others operating more extensive fleets of jets and helicopters.
- **Part 121 Operators:** Air carriers under Part 121 operate commercial flights on scheduled services. With more than 7,500 aircraft registered in the U.S. alone, these operators represent a significant market for an AI-driven FRAT. While Part 121 operators are already mandated to use Safety Management Systems, many can benefit from the enhanced features and real-time data integration of the AI-driven FRAT, which would further improve operational safety and risk management.

Given the FAA's upcoming mandate for SMS compliance, both Part 91 and Part 135 operators represent a strong opportunity for early adoption of AI-driven FRAT tools. Additionally, with over 55 million ATC movements registered in 2023, the demand for pre-flight risk analysis tools is growing across all operator categories, including Part 121 air carriers.

9. IMPLEMENTATION AND DEPLOYMENT CONSIDERATIONS

Developing and deploying an AI-based FRAT requires careful planning, especially regarding offline functionality and data integration:

- **Offline Functionality:** The tool will store essential data locally, ensuring it continues to provide risk assessments even in areas without internet connectivity. Periodic synchronization will be required to update the data.
 - **Integration with Existing Systems:** The tool will be designed to integrate seamlessly with existing EFBs (Electronic Flight Bags) and other operator systems, ensuring a smooth transition for users.
 - **Regulatory Compliance:** The tool will comply with FAA regulations, including data privacy and security measures.

11. CONCLUSION

As the aviation industry moves toward proactive safety management, the need for smarter, more adaptive tools is becoming increasingly clear. Traditional FRATs, with their reliance on static data and manual inputs, are no longer sufficient to meet the complex demands of modern aviation operations.

The AI-driven Flight Risk Assessment Tool presented in this white paper addresses these challenges by offering a real-time, dynamic approach to risk assessment. By integrating diverse data sources – ranging from weather updates to pilot fatigue levels–, the tool provides a comprehensive analysis that goes beyond simple risk scoring. Its ability to generate tailored mitigation strategies further enhances decision-making and reduces human error, ultimately contributing to safer flights.

With the upcoming FAA mandate requiring SMS implementation by 2027 for Part 135 and certain Part 91 operators, the opportunity for adopting this advanced tool is now. Not only does it meet the new regulatory requirements, but it also offers a competitive advantage by improving safety and operational efficiency.

We invite operators, regulators, and stakeholders to explore how this AI-driven FRAT can transform aviation safety practices.
